ABSTRACT
This study was designed to investigate the possible ameliorative effects of mulberry fruits on oxidative damage induced by γ-irradiation in male rats. Gamma-irradiation (2.5 Gy x 3 delivered every other day) resulted in a significant decrease of hepatic glutathione content (GSH) and the activity of xanthine dehydrogenase (XDH), superoxide dismutase (SOD) and catalase (CAT). The level of insulin and testosterone as well as the concentration of high density lipoprotein-cholesterol (HDL-C) showed a decrease. A remarkable increase of malondialdehyde (MDA) concentration and xanthine oxidase activity was elevated in the liver. The activity of some liver enzymes, the level of glucose and the concentrations of total cholesterol (TC), triglycerides (TG), low density- and very low density lipoprotein-cholesterol showed a significant increase. Administration of mulberry fruit powder (MFP) to γ-irradiated rats was found to offer protection against γ-irradiation induced oxidative stress by elevating the activity of antioxidant enzymes, enhancing liver function in addition to improving the lipid metabolism. From all results collected in this study, it could be concluded that the berries might be considered a natural antioxidant substance that can protect from radiation hazards.

Key words: Gamma–irradiation / Mulberry fruits / Antioxidants / Insulin / Testosterone

INTRODUCTION
All living organisms are exposed to some amount of radiation coming from outer space or emitted from the radioisotopes present in the environment (1). Radiations are commonly used in a number of medical and industrial situations; however, their prooxidative effects limit their applications (2). The deleterious effects of ionizing radiation in biological systems are commonly mediated through the generation of reactive oxygen species (ROS) causing oxidative damage in several organs (3).

The scavenging of free radicals and inhibition of lipid peroxidation has been suggested to be the key target activities for developing successful radioprotection strategies (4&5). Natural antioxidants play a major role by continuously inactivating ROS to keep only a small amount necessary to maintain normal cell function (6). Considerable epidemiological evidence has been gathered to suggest an association between consumption of fruits containing antioxidants and a reduced risk of certain chronic diseases (7).

Mulberry (Morus alba L.) belongs to the family Moraceae. Mulberry fruit is widely regarded as a nutritious food and it can be eaten freshly or widely used in the production of wine, fruit juice, jam and canned food (8). Mulberry fruit is not only used as fruit but also it has been used effectively in natural medicine for the treatment of sore throat, fever, hypertension and anemia (9). Moreover, mulberry fruit is used to protect against liver and kidney damage, strengthen the joints, improve eyesight and have anti-aging effects (8). Anthocyanins and water extracts from mulberry fruit can scavenge free radicals, inhibit low-density lipoprotein (LDL) oxidation, and have beneficial effects on blood lipid and atherosclerosis (10).
Therefore, the present study was undertaken to investigate the possible ameliorative effects of mulberry fruits on oxidative damage resulting from exposure of normal male rats to $\gamma$-radiation.

**MATERIAL AND METHODS**

**Materials and Plant Preparation:**

Standard commercial rodent diet and fresh purple-colored mulberry fruits were purchased from the local market (Cairo, Egypt). All berries were dried at 70°C for 4 days and grounded to powder $^{11}$. 

**Radiation Facility:**

Whole body gamma irradiation of rats was performed using a Canadian gamma cell-40, ($^{137}$Cs) housed at the National Center for Radiation Research and Technology (NCRRT), Cairo, Egypt. The dose rate was 0.43 Gy/min at the time of the experiment. Rats were exposed to fractionated dose of 7.5 Gy $\gamma$-irradiation administered as 2.5 Gy every other day.

**Determination of total phenolic compounds:**

The concentration of total phenolic compound was measured by a modified Follin-Ciocalteu colorimetric method $^{12}$. Briefly, a sample diluted was added to a test tube containing 1.58mL of distilled water. Folin-Ciocalteu reagent of 100 $\mu$L was added, and the tube was stirred and allowed to stand at room temperature for 8min. 300 $\mu$L of $\text{Na}_2\text{CO}_3$ (7%, w/v) was added to the mixture and the absorbance was measured at 765nm after 120 min at room temperature using a spectrophotometer. The results were expressed as milligram of gallic acid equivalents (GAE) per gram fresh matter of fruit (mg GAE/ g fruit).

**Determination of Antioxidant Activity by the 2,2-Diphenyl-1-Picrylhydrazyl (DPPH):**

DPPH assay was determined by a specific method described $^{13}$. Each sample (0.5 mL) was added to 0.5mL of 0.4m MDPPH in methanol. The mixture was shaken vigorously and allowed to stand for 30min; the absorbance of the resulting solution was measured at 517nm with a spectrophotometer. Percent inhibition of DPPH radical was calculated for each dilution of berry extract according to formula: 

$$%\text{inhibition} = \left(\frac{A_{\text{DPPH}} - A_{\text{plant}}}{A_{\text{DPPH}}}\right) \times 100,$$

where $A_{\text{DPPH}}$ is the absorbance value of the DPPH versus blank solution and $A_{\text{plant}}$ is absorbance value of the sample solution. A lower level of absorbance indicated a stronger radical scavenging activity.

**Experimental Animals:**

Adult male albino rats, reared in NCRRT animal house, were used in the present experiments. Matched weight animals (150±10g) were selected and housed in plastic cages under controlled condition and fed on standard commercial rodent diet.

**Experimental design:**

Male albino rats (24 animals) were randomly divided into four groups as follow: - **Group (C):** (control group) rats fed on balanced diet for 6weeks, **Group (MFP):** rats fed on balanced diet contained 1% mulberry fruits powder (MFP) for 6 weeks, **Group (Irr.) :** (irradiated group) rats fed on balanced diet and were exposed at the 1st week of the experiment period (6 weeks) to fractionated $\gamma$-irradiation dose of 7.5 Gy administered as 2.5 Gy every other day and **Group (Irr. +MFP):** rats fed on
balanced diet contained 1% MFP and exposed at the 1st week of the experiment period (6 weeks) to fractionated $\gamma$-irradiation dose of 7.5 Gy administered as 2.5 Gy every other day.

At the end of the experiment, animals from each group were sacrificed 24 hrs post the last dose of treatment. Blood samples were collected though heart puncture after light anesthesia and allowed to coagulate and centrifuged to obtain serum for biochemical analysis. Also, liver tissue was removed for biochemical investigation.

**Biochemical Analysis:**

The lipid peroxidation was determined colorimetrically as malondialdehyde (MDA) according to Yoshioka et al. (14). Hepatic xanthine oxidase (XO) and xanthine dehydrogenase (XDH) were determined according to Kaminski and Jeweszka (15). Whereas, the value of hepatic glutathione content (GSH) and the activity of superoxides dismutase (SOD) and catalase (CAT) were measured by the method of Gross et al. (16), Minami and Yoshikawa (17) and Aebi (18), respectively. In addition, total cholesterol (TC), triglycerides (TG) and high-density lipoprotein-cholesterol (HDL-C) were determined according to procedure described by Allain et al. (19), Fossati and Prencipel (20) and Demacker et al. (21), respectively, while low-density lipoprotein cholesterol and very low-density lipoprotein-cholesterol were evaluated according to Friedwald et al. (22) and Norbert (23) formulas, respectively by the following equations: LDL-C (mg/dl) = TC - (TG/5+HDL-C), vLDL (mg/dl) = TG/5. The activity of serum aspartate transaminase (AST) and serum gamma glutamyl transferase (GGT) was assessed according to Reitman and frankel (24), serum alkaline phosphatase activity (ALP) was assessed according to Kind and King (26), and serum total bilirubin was determined using the method reported by Malloy and Evelyn (27). Serum glucose was evaluated by the method of Trinder (28). Finally, the serum testosterone concentration was measured by the enzyme linked immunosorbent assay (ELISA) according to the method of Engrall and Perlman (29) and also insulin hormone level was determined by radioimmunoassay kit supplied by Diasari, Italy.

**Statistical analysis:**

Results were presented as mean ± SE (n = 6). Experimental data were analyzed using one way analysis of variance (ANOVA). Duncan’s multiple range test was used to determine significant differences between means. Statistical analyses were performed using computer program Statistical Packages for Social Science (SPSS) (30). Differences between means were considered significant at $P < 0.05$

**Results**

The amount of total phenolic compounds and the total antioxidant activity of mulberry fruit (MF) are shown in Table (1); the results showed that the total phenolic contents was 517.35 mg GAE/g while the total antioxidant activity of MF was 230.25 $\mu$g/mL fresh matter of fruit.

The data presented in Table (2) revealed a significant decrease in the value of hepatic GSH content and the activity of XDH, SOD and CAT activity associated with a significant increase in MDA level and XO activity of rats exposed to γ-radiation as compared to the corresponding values of control and other groups. While rats received MFP after γ-radiation exposure exhibited a lower concentration of MDA and XO activity and higher level of GSH as well as SOD and CAT activity compared to those of the γ-irradiated group.

Values in the same row with different superscripts are significantly different at P<0.05.

As a result of γ-irradiation of rats, levels of TC, TG, LDL-C and vLDL-C were highly increased with a significant decrease in HDL-C concentration as compared with control, while treatment of rats with MFP after γ-irradiation minimized the hyperlipidemic effects of γ-irradiation by reducing the concentration of TC, TG, LDL-C and vLDL-C and elevated the level of HDL-C as compared to irradiated group.

Finally, the data summarized in Table (5) indicated that exposure of rats to $\gamma$-radiation resulted in an obvious rise in the glucose concentration associated with reduced level of insulin and testosterone. On the other hand, it was noticed that MFP administration to $\gamma$-irradiated rats reduced the level of glucose as well as enhanced the level of insulin and testosterone.

**DISCUSSION**

It is well documented that dietary antioxidants play an important role in mitigating the damaging effects of oxidative stress on cells. Yang et al. (31) indicated that mulberry fruit is a natural health food with antioxidant effects, and these beneficial effects may be due to phytochemical constituents, including fiber, fatty acids, phenolic compounds, flavonoids, anthocyanins, vitamins and trace elements.

Many reports have revealed that the physiological function of natural foods can be attributed to the antioxidative capacity of their phenolic components. The results in table 1 demonstrated that the total phenolic content (TPC) of mulberry fruit was 517.35 mg GAE/g whereas the total antioxidant activity was 230.25 $\mu$g/mL. These results are in agreement with those found by Kaewkaen et al (41).

According to the data presented, it appears that the detrimental damage of radiation is associated with the alteration of XOR system and conversion of XDH into XO activity. The significant increase in XO activity might be attributed to radiation-induced hypoxia where insufficient oxygen availability elevates calcium concentration, which activates protease capability of converting the dehydrogenase to oxidase form (32). Also, the level of MDA was elevated in the serum of untreated irradiated animals. The increased thiobarbituric acid reactive substances (TBARS) level in irradiated rats could be attributed to the peroxidation of membranes lipid resulting in cellular structure modifications and oxygen radicals- mediated tissue damage (33).

In the present study, the activity of superoxide dismutase (SOD) and catalase (CAT) was significantly decreased in irradiated rats. The existence of a mutually supportive relationship between enzymatic antioxidants; SOD and CAT, against accumulation of ROS inactivates the superoxide anion and peroxide radicals by converting them into water and oxygen. In this study, the observed decrease in SOD activity might be due to inactivation of the enzyme possibly due to increased superoxide radical production or an inhibition by the $H_2O_2$ as a result of corresponding decrease in the activity of CAT which selectively degrades $H_2O_2$. In previous studies, activities of SOD, CAT and GPx have been reported to decrease in the liver of irradiated rats (34). The significant decrease in GSH levels observed with untreated irradiated animals might be lead to a decrease in protection against oxidants. This decrease could be due to an enhanced utilization in large amount to combat the radiation-induced free radical damage, as glutathione is a major non-enzymatic antioxidant (35). Similar decrease in hepatic GSH (33) has been reported following gamma irradiation of rats.
In this study, irradiated rats treated with mulberry fruits powder (MFP) showed a significant decrease in the level of MDA content and XO activity with concomitant significant increase in the activity of XDH, SOD and CAT, and in the content of GSH. Thus, MFP has the potential of being an anti-peroxidative agent and as an antioxidant. Yang et al. (31) reported that MFP contained vitamin C and low levels of vitamin E in addition to anthocyanins and flavonoids, all of which are powerful natural antioxidants that increase SOD and GSH-Px activities, and decrease TBARS concentration and improve lipid profiles in rats (36). In addition, mulberry fruit contains many trace elements including Cu, Mn, Zn and Fe which are necessary components of SOD (31). Among these, Cu and Mn are prosthetic groups of SOD and play a decisive role in its enzyme activity. Zn stabilizes the structure of SOD (37). Se is an important element of GSH-Px, which regulates lipid metabolism, prevents fatty liver formation and improves antioxidant ability in rats (38).

The present results revealed that the levels of TC, TG, LDL and vLDL-C in serum were significantly higher in irradiated rats than those of the control group. On the other hand, radiation exposure resulted in a significant decrease in HDL-C level in serum of the irradiated rats. Significant increase in the levels of serum lipid profile and LDL are demonstrated post radiation exposure of rats, possibly as a result of liver injury. This indicates that ionizing-radiation-induced oxidative stress which might alter hepatic lipid metabolism and serum lipoproteins. It seems that there is an association between radiation-induced oxidative stress and elevated levels of lipid fractions and LDL (39). This association is similarly observed in other conditions characterized by increased oxidative stress (40). Therefore, it is suggested that oxidative stress might be an important determinant of altered lipid metabolism due to radiation exposure (41).

Administration of MFP to irradiated rats resulted in significant declines in serum lipid profile, LDL-C and vLDL-C associated with remarkable elevation in HDL-C as compared to γ-irradiated group. The physiological effects of mulberry as an antioxidant take place via its contents like flavonoid, therefore suggesting their role in prevention of coronary heart disease (42) including atherosclerosis. Wan et al. (43) and Jenkins et al. (44) reported that flavonoids may decrease the risk of cardiovascular disease by lowering LDL: HDL ratio and reducing oxidized LDL in human and make LDL less susceptible to oxidative stress. Flavonoids may work by making liver cells more efficient to remove LDL-C from blood by increasing the LDL receptor densities in liver and by binding to apolipoprotein B (45). Also, the increase in HDL-C concentration could protect the LDL against oxidation in vivo because lipids in HDL are preferentially oxidized before those in LDL (46).

The activity of ALT, AST, ALP and GGT as well as the level of total bilirubin in serum showed a significant rise following γ-irradiation exposure. The increase in aminotransferases activity by radiation may be due to the damage of cellular membranes of hepatocytes, which in turn leads to an increase in the permeability of cell membranes and facilitates the passage of cytoplasmic enzymes outside the cells leading to the increase in the aminotransferases activity in liver and blood serum (47). Also, it is proposed that oxidative stress is linked to the organ damage following exposure to ionizing radiation (41 & 48).

However, the activity of liver enzymes was decreased as a result of MFP administration to γ-irradiated rats. Several studies revealed that mulberry fruit, leaves, bark and branches have used in Chinese medicine to treat fever, facilitate discharge of liver, protect the liver damage and lower blood pressure (49). Hsu et al. (50) investigated the protective mechanisms of mulberry water extracts (MWEs) in carbon tetrachloride (CCl4)-induced hepatic injury and observed that the levels of serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and alkaline phosphatase (ALP) were reduced via cotreatment with MWEs compared with CCl4 treatment alone. Also, the authors concluded that MWEs exhibit protective and curative effects against CCl4-induced liver damage and fibrosis via decreased lipid peroxidation and inhibited proinflammatory gene expression.
In the work, rats exposed to gamma radiation had a significant elevation in serum glucose level and noticeable reduction in insulin concentration compared to the control group. Ellefson and Caraway (51) stated that hyperglycemia may be caused by metabolic disorder as a result of endocrine dysfunction and increased level of glucose. The recorded hyperglycemia could be attributed to endocrine abnormalities induced by irradiation of rats that promote the secretion of peptide which has relation to carbohydrate metabolism by increasing glycogen synthesis in liver (52). Lee et al. (53) and Hamza and Osman (54) attributed the lowering effect of γ-irradiation on insulin level to the production of free radicals that induced oxidative stress resulted in reduction in insulin secretion and DNA damage.

Results of γ-irradiated rats received MFP revealed an obvious reduction in glucose level and elevation in insulin concentration in comparison to γ-irradiated group. The antidiabetic activity of mulberry leaf extract had also been reported by many researchers (55). Studies supporting the usage of mulberry reduced blood glucose in rats with diabetes induced by streptozotocin or alloxan (56, 57). In addition, mulberry has long been used in Chinese medicine for the prevention and treatment of diabetes, because, they contain chemical compounds that suppress high blood sugar levels (hyperglycemia) following a carbohydrate-rich meal. Mudra et al. (58) concluded that the co-ingestion of mulberry extract with 75 g sucrose significantly reduced the increase in the blood glucose level. Moreover, Li et al. (59) observed a significant decline in blood glucose accompanied with evident increase in plasma insulin level in diabetic mice treated with the hybrid of 1-deoxynojirimycin and polysaccharide (HDP) from mulberry. The authors reported that HDP could protect pancreatic β-cells from damage induced by alloxan due to the ability to scavenge the free radical and repair the destroyed pancreatic β-cells and restored the serum insulin in HDP treated mice to normal.

In the present investigations, a significant reduction in the concentration of testosterone was observed as a result of γ-irradiation of rats. However, the value of this hormone was obviously increased post treatment of γ-irradiated rats with MFP. Liu et al. (59) and Michael and Amer (60) found that the level of testosterone was decreased after whole-body irradiation dose of 4 and 5 Gy due to alterations in DNA-single strand break, cell apoptosis and oxidative stress. Popoff and Kapich (61) observed a positive correlation between a decline in testosterone affinity and exposure to gamma irradiation. Also, Hamza and Osman (54) reported that γ-irradiation exposure (6 Gy) resulted in a significant decline in testosterone concentration due to generation of free radicals.

However, the effect of MFP on testosterone level might be attributed to its phenolic contents that have antioxidant capacity and prevent oxidative damage induced by γ-irradiation. Oi-Kano et al. (62) proposed the mechanism of phenolic compounds supplementation enhances lipid and protein metabolism owing to hormonal regulation by the stimulation of noradrenalin secretion, thereby affecting the levels of steroid hormones, including testosterone and corticosterone, and other hormones in rats. Also the effect of MFP could be linked to the abundance of flavonoids (which is an effective aromatase inhibitor) (63). The cytochrome P-450 aromatase is required for the conversion of androgens to estrogens and hence aromatase inhibitors would decrease the concentration of estrogens and maintain a higher level of testosterone.

CONCLUSION

In conclusion, the present study revealed that the mulberry fruit is a potential functional food that can protect against oxidative damage induced by gamma-irradiation of rats through its positive effects on the activity of some antioxidant enzymes, liver enzymes, elevation of the level of insulin and testosterone, inhibition of lipid peroxidation as well as improvement of lipid profile. Moreover, the ameliorating effects of MF might be attributed to its phenolic and flavonoid contents that possess antioxidant activity.
